DOI: <https://doi.org/10.33545/26630427.2022.v5.i1a.111>

Abstract

Rural and urban Diabetic patients don't get adequate knowledge, guidance and supervision of self-administration of insulin injection. So Diabetic patients in rural and urban areas doesn't know how to take insulin injection by self, when they inject, and even if they are taking their insulin injection they will use primary health centre nursing staff, community health nurse or else and some time if they are using pen type syringe also they will not use self-administration of insulin.

Methods: This was a structured teaching programme on knowledge and practice the study was carried out in Kenguri rural community at Bangalore. 60 diabetic clients were selected by purposive sampling technique; structured interview schedule was used to collect the data, the pre-test structured teaching programme conducted by administering knowledge and practice questionnaire on self-administration of insulin injection, and the 7th day post test was conducted by using the structured teaching programme.

Result: The total of 60 participants enrolled with 30 in each group. There was improvement in knowledge and practice after the structured teaching programme and is statistically significant. The overall mean knowledge and practice score present in the pre-test is 38% and 39.2%. And in the post-test 72.67% and 78.67% so there is enhancement of knowledge and practice score found to be 25.33% and 39.47%. The mean knowledge and practice score during pre-test is 11.4 and 5.88. And in post-test 21.8 and 11.8. The overall mean knowledge and practice score present of pre-test found to be 38% and 39.2% and the post mean knowledge and practice score was 72.67% and 78.67% it shows the enhancement of knowledge and practice after structured teaching programme.

Keywords: Self-administration of insulin injection, diabetic clients, structure teaching programme

Introduction

Background of the study

Rural and urban Diabetic patients don't get adequate knowledge, guidance and supervision of self-administration of insulin injection. So Diabetic patients in rural and urban areas doesn't know how to take insulin injection by self, when they inject, and even if they are taking their insulin injection they will use primary health centre nursing staff, community health nurse or else and some time if they are using pen type syringe also they will not use self-administration of insulin.

So structured teaching programme is given to Diabetic patients regarding self-administration of Insulin injection technique, in order to improve knowledge and practice.

Objectives

- To assess the existing knowledge and practice regarding self-administration of insulin injection among diabetic clients.
- To evaluate the effectiveness of structured teaching programme regarding self-administration of insulin injection among diabetic clients.
- To find out the relationship between knowledge and practice regarding self-administration of insulin injection among diabetic clients.
- To find out the association between knowledge and practice score with selected demographic variables

Hypotheses

- **H₁** - There will be a significant difference between pretest and posttest knowledge score of diabetic clients regarding self-administration of insulin injection after administration of STP.
- **H₂** - There will be a significant difference between pre and posttest practice score of diabetic clients regarding self-administration of insulin injection after administration of STP.
- **H₃**- There will be a significant relationship between pretest and posttest knowledge and practice score on self-administration of insulin injection among diabetic clients.
- **H₄** - There will be a significant association between knowledge and practice score on self-administration of insulin with selected demographic variables.

Methods: One group pre-test and post design was used to assess the effectiveness of structured teaching programme on self-administration of insulin injection among diabetic

clients selected urban and rural community. In view the nature of the problem accomplishes the objectives of the study. Structured teaching programme was prepared and structured knowledge and practice questionnaire was used to assess the effectiveness of structured teaching programme. The study was carried out in Kengeri rural community at Bangalore. 60 diabetic clients were selected by purposive sampling technique; structured interview schedule was used to collect the data, the pre-test structured teaching programme conducted by administering knowledge and practice questionnaire on self-administration of insulin injection, and the 7th day post test was conducted by using the structured teaching programme.

Major findings of the study were Frequency and percentage and X² of knowledge score with selected demographic variables

Mean, mean%, standard deviation, and R-value of pre-test knowledge and practice regarding self-administration of insulin injection among diabetic clients.

There was significant knowledge association found between such as occupation (χ^2 18.71), monthly income (χ^2 8.46), Duration of illness (χ^2 10.21) at $p < 0.05$ level. For these demographic variables H_4 is accepted. There was no significant relationship found between the variables such as age of diabetic clients (χ^2 2.1), Gender (χ^2 1.38), Educational status (χ^2 7.33), Religion (χ^2 0.57), History of

diabetes (χ^2 0.94), Duration of treatment (χ^2 3.82), Injection by self (χ^2 1.07), Urine test (χ^2 0.4), Type of syringe (χ^2 1.75), Site of injection (χ^2 0.59), Time of injection (χ^2 3.98), For this demographic variable H_4 was rejected.

Frequency and percentage and X² of practice score with selected demographic variables

Table 2: Frequency and percentage and X² of practice score with selected demographic variables

Such as Educational status (χ^2 8.2), Occupation (χ^2 21.42), Monthly income (χ^2 10.7), Duration illness (χ^2 12.8), at $P < 0.05$ level. For this, demographic variables H_4 is accepted. There was no significant relationship found between the variables such as age of diabetic clients (χ^2 2.61), Gender (χ^2 2.29), Religion (χ^2 1.91), History of diabetes (χ^2 2.07), Duration of treatment (χ^2 3.39), Injection by self (χ^2 1.33), Urine test (χ^2 2.3), Type of syringe (χ^2 0.78), Site of injection (χ^2 0.38), Time of injection (χ^2 2.14), For this

demographic variable H_4 was rejected. The finding of the present study revealed that the knowledge and practice regarding self-administration of insulin injection. The overall mean, knowledge and practice score present in the pre-test is 38% and 39.2%, which is slightly less. This shows there is lack of knowledge and practice among rural diabetic clients regarding self-administration of insulin injection.

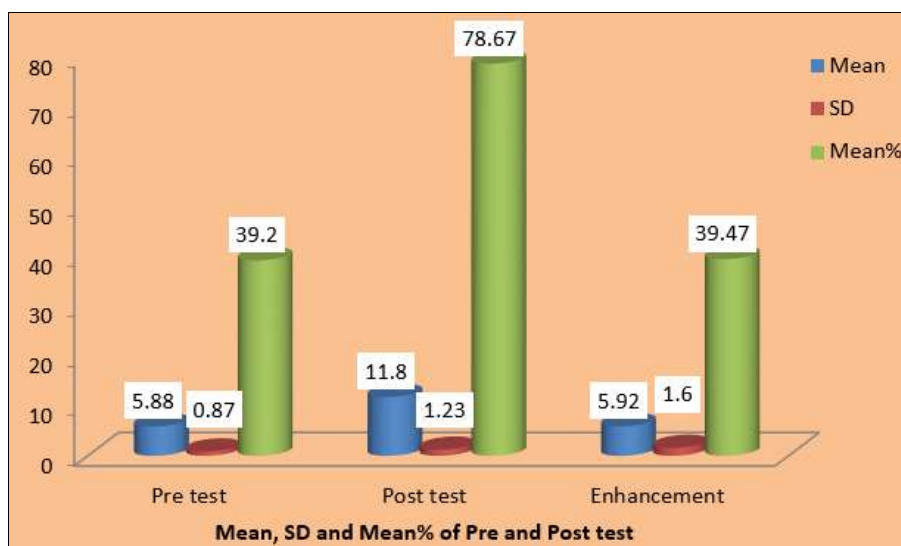

Fig 1: Mean, mean%, standard deviation, and R-value of post-test knowledge and practice.

The present study confirms that there was improvement in knowledge and practice after the structured teaching programme and is statistically significant. The overall mean knowledge and practice score present in the pretest is 38% and 39.2%. And in the posttest 72.67% and 78.67% so there is enhancement of knowledge and practice score found to be 25.33% and 39.47%. The mean knowledge and practice score during pretest is 11.4 and 5.88. And in posttest 21.8 and 11.8. The overall mean knowledge and practice score present of pretest found to be 38% and 39.2% and the post mean knowledge and practice score was 72.67% and

78.67% it shows the enhancement of knowledge and practice after structured teaching programme. Hence, research hypothesis H_1 is accepted since there is significant changes found between pretest and posttest knowledge score after structured teaching programme regarding self-administration of insulin injection among diabetic clients at 5% level and research hypothesis, H_2 is since there are significant changes found between pretest and posttest practice score after structured teaching programme regarding practice self-administration of insulin injection among diabetic clients at 5% level.

There was significant relationship between knowledge and practice regarding self-administration of insulin injection. The overall mean knowledge and practice score present in the pre-test is 38% and 39.2%. And in the post-test 72.67% and 78.67%. Correlation coefficient between knowledge and practice on pre-test and post-test was 0.18 and 0.56, so it is positively correlated hence H3 is accepted

Analysis shows demographic variables in the study like respondent's occupation, monthly income, duration of illness in the knowledge level found significant since H4 is accepted. But in the respondents knowledge score age, gender, educational status, religion, history of diabetes, duration of treatment, injection by self, urine test, type of syringe, site of injection, time of injection in the knowledge score level found non-significant. So H₄ is rejected, and H₀₄ is accepted.

The respondent's educational status, occupation, monthly income, duration of illness with practice score of respondents found significant. Hence H4 is accepted. Whereas age, gender, religion, history of diabetes, duration of treatment, injection by self, urine test, type of syringe, site of injection, time of injection with practice score is found to be none significant H₀₄ is accepted.

Conclusion

Further effectiveness of structured teaching programme was tested by inferential statistics using paired test. A significant difference was found between pre-test and post-test knowledge scores of diabetic clients including increase in knowledge after structured teaching programme. Hence research hypothesis H₁ accepted.
